

The figure consists of 12 vertical grayscale photographs arranged in a single row. Each photograph shows the side profile of a person's head and neck. The sequence of images from left to right demonstrates a range of head positions, likely corresponding to different levels of neck flexion or extension. The person's face is partially visible, and the focus is on the neck area where a cervical collar would be worn. The images are used to illustrate the variability in neck shape and position that the study aims to address.
